Serum Melatonin Levels in Patients with Sudden Sensorineural Hearing Loss

ABSTRACT

Objective: This study aimed to investigate the serum melatonin levels of patients with idiopathic sudden sensorineural hearing loss (ISSNHL).

Methods: This study enrolled 22 patients with ISSNHL and 22 asymptomatic healthy volunteers. The subjects underwent pure tone audiometry and serum melatonin levels were measured.

Results: The patient group was composed of 12 women (mean age, 46.41±7.8) and 10 men (mean age, 48±6.46), and the control group was composed of 12 women (mean age, 40.25±5.28) and 10 men (mean age, 38.4±27.08). The serum melatonin levels were significantly lower in the patient group than in the control group (p≤0.001). A statistically significant strong negative correlation was found between serum melatonin level and severity of hearing loss (r=−0.644; p=0.001).

Conclusion: Serum melatonin levels of patients with ISSNHL were lower than controls. A statistically significant strong negative correlation was found between serum melatonin level and the severity of hearing loss.

Keywords: Sudden hearing loss, melatonin, antioxidant

ÖZ

Amaç: Bu çalışmanın amacı, idiyopatik ani sensörinöral işitme kaybı (İASİK) olan hastaların serum melatonin düzeylerini ortaya koymaktır.

Bulgular: Hasta grubunda 12 kadın (ortalama (ort.) yaş: 46,41±7,8) ve 10 erkek (ortalama yaş: 48±6,46) vardı. Kontrol grubunda 12 kadın (ortalama yaş: 40,25±5,28) ve 10 erkek (ortalama yaş: 38,4±27,08) vardı. Serum melatonin düzeylerinin hasta grubunda kontrol grubuna göre anlamlı dereceye düşük olduğu saplandı (p≤0,001). Serum melatonin seviyesi ile işitme kaybının şiddeti arasında istatistiksel olarak anlamlı güçlü negatif bir korelasyon vardı (r=−0,644; p=0,001).

Sonuç: İASİK olan hastaların serum melatonin düzeyleri kontrol grubundan daha düşüktü. Serum melatonin seviyesi ile işitme kaybının şiddeti arasında istatistiksel olarak anlamlı güçlü negatif bir korelasyon vardı.

Anahtar Sözcüklər: Ani işitme kaybı, melatonin, antioxidant

Introduction

The etiology of sudden hearing loss is only known in 10% of the cases, and it is still classified as idiopathic in 90% of the cases. Although idiopathic sudden sensorineural hearing loss (ISSNHL) is an otologic emergency, its etiopathogenesis is not known exactly. Although some theories attempt to explain the pathogenesis of ISSNHL, such as viral infections, membrane rupture, immune-mediated inner ear disease, vascular events, genetic and acquired factors, none of these theories have yet been proven (1).

Hair cells are high-energy and oxygen-consuming cells, and the most important factor for this is the mitochondrial electron transport chain. Reactive oxygen species (ROS), which appears as a result of mitochondrial changes during hypoxia, can trigger cell death by damaging lipids, proteins and deoxyribonucleic acid (2).

ROS causes apoptosis by damaging the inner hair cells. This hypothesis has been verified by showing ROS in the perilymphatic fluid of the inner ear of patients with deep sensorineural hearing loss throughout cochlear implantation surgery (3). Many studies have demonstrated that ROS is linked to many diseases that may cause hearing loss, including noise, drug use, genetic hearing loss, presbycusis, and Meniere syndrome (4-7).

Melatonin is a hormone secreted by the pineal gland, has a direct antioxidant effect, is a potent scavenger of ROS and enhances the activity of antioxidant enzymes (8).

Melatonin is also detected in the organ of Corti, basilar membrane, spiral ligament, stria vascularis and cochlear nerve (9). Lasisi and Fehintala (10) had shown that low plasma melatonin level is important in the development of age-related high-frequency hearing loss.

In this study, we aimed to investigate the serum melatonin levels in patients with ISSNHL to determine whether serum melatonin levels have an effect on the pathophysiology of ISSNHL.

Methods

Study Population

The study was planned with 31 patients diagnosed with ISSNHL and 22 healthy volunteers in Uskudar State Hospital Otolaryngology Clinic. The diagnosis of ISSNHL was made according to criteria of the American Academy of Otolaryngology-Head and Neck Surgery (11). Patients with conductive hearing loss, a history of otologic surgery, head trauma, or barotrauma during the previous 4 weeks, neurologic disorders predisposing to hearing loss, accompanying upper respiratory tract infection, autoimmune diseases, vestibular symptoms, fluctuating hearing loss in the last 4 weeks and hearing loss due to pathological brain mass in magnetic resonance imaging were excluded from the study. Following patient screening, nine patients were excluded from the study. The study included 22 patients diagnosed with ISSNHL. The control group was composed of 22 healthy volunteers, i.e. had no ear problems and no chronic systemic disease. Complete history taking, physical examination, laboratory workup, bleeding profile, venereal diseases research laboratory test and antinuclear antibody test were performed in both groups. None of the subjects were taking any antioxidant vitamins.

The study was approved by the ethics committee of Zeynep Kamil Women’s and Children’s Diseases Training and Research Hospital (Protocol number: 109, date: 27.06.2018).

Audiological Evaluation

All patients were tested for pure tone audiometry for both ears up to 8000 Hz frequency starting at 250 Hz frequency by international standards. Pure-tone average was determined by calculating the mean of the 500, 1000, 2000 and 4000 Hz thresholds. All patients underwent a tympanogram test. Hearing impairment was assessed according to the international standard criteria defined by the World Health Organization Prevention of Deafness and Hearing Impairment standard 97.3 (12).

Laboratory Study

The human melatonin levels were measured with a competitive enzyme-linked immunosorbent assay (ELISA) using commercial kits (Elabscience; lot no. QQQB5LYL, PRC) and an ELISA reader (Multiskan FC® Microplate Photometer; Thermo Scientific, USA).

In this study, 96-well ELISA plates precoated with anti-human melatonin antibodies were used. The standards and samples were added to the micro ELISA plate wells for binding to the specific antibody. Then, biotinylated detection antibody was added immediately. During the reaction, human melatonin in the sample or standards compete for binding with human melatonin antibody. After a specific incubation period, excess conjugate and independent sample or standards were washed from the plate, and avidin that conjugated to horseradish peroxidase was annexed to every well and incubated. After these procedures, a tetramethylebenzidine substrate solution was supplemented to each well. The enzyme-substrate reaction was finished by the supplement of a stop solution, and the colour shift was measured spectrophotometrically at a wavelength of 450 nm. The human melatonin concentrations in the samples were calculated according to the optical density (OD) in the standard curve and then determined by comparing the OD of the samples to the classical curve. The results were demonstrated using the pg/mL unit. For sensitivity levels, the minimum definable dose of melatonin was 9.38 pg/mL, and the detection range was 15.63-1000 pg/mL.

Statistical Analysis

In this study, IBM SPSS Statistics version 22 was used for statistical analysis. Shapiro-Wilk test was used to evaluate the normal distribution of the parameters. Descriptive statistical methods (mean, standard deviations and median value) were calculated. Mann-Whitney U test was used to compare nonparametric data between groups. Spearman correlation test was used to determine the correlation of nonparametric data between two groups. The r value was evaluated between −1 and +1. Significance was assessed at p<0.05 level.
Results

This study enrolled 22 patients with ISSNHL and 22 asymptomatic healthy volunteers. The patient group was composed of 12 women and 10 men. The female patients were 32-62 years old (mean age, 46.41±7.80 years). The male patients were 38-55 years old (mean age, 48±6.46 years). The control group was composed of 12 women and 10 men. The female volunteers were 30–48 years old (mean age, 40.25±5.28 years). The male volunteers were 27–47 years old (mean age, 38.4±27.08 years) (Table 1).

Type A tympanogram was obtained in both groups. In the pure tone audiometry test, the mean values of the right air, right bone, left air and left bone were 34.36±21.66 dB, 29.40±20.88 dB, 40.72±30.33 dB and 35.09±27.77 dB, respectively (Table 1). The serum melatonin level averages of the patients and controls were 51.32 ± 12.45 and 78.79 ± 29.39 pg/mL, respectively. The serum melatonin levels were significantly lower in the patient group than in the control group (p≤0.001) (Table 2).

A statistically significant strong negative correlation was found between serum melatonin and severity of hearing loss in the patient group (r=−0.644; p=0.001). The coefficient of determination ($r^2$) between these two variables was 0.232 (Table 3) (Graphic 1).

Discussion

The pathogenesis of ISSNHL can not be clearly identified because histopathological examination was not possible. Its causes include viral infections, autoimmune inner ear diseases, cochlear vascular pathologies or a combination of these mechanisms (13,14).

Merchant et al. (15) demonstrated that ISSNHL may be the result of the abnormal activation of cellular stress pathways within the cochlea and that nuclear factor kappa B (NF-kB) induces oxidative stress, inflammatory cytokines and other stress-related proteins. This hypothesis was supported by the pathological activation of NF-kB, which stimulates the production of inflammatory cytokines and other proteins due to oxidative stress since the cochlear microcirculation is very sensitive to changes in blood flow velocity, and dysfunction of the cortical organ occurs very quickly even in limited perfusion disorders (16).

Different models of experimentally induced reperfusion injury confirm that free radicals originating from oxygen play a significant role. Clerici and Yang (17) found high-frequency compound action potential threshold shifts in an animal study examining the specific effects of ROS production on cochlear function. Bielefeld et al. (18) found similar findings in a study evaluating the effect of superoxides on inferior colliculus-induced potential thresholds and hair cell damage. In a study comparing the ROS and total antioxidant status (TAS) concentrations on the effect of oxidative stress on ISSNHL, ROS levels were considerably higher in the patient group than in the healthy group, while no significant difference was found between the TAS levels (19).

Dysfunction of endothelial cells leads to an increase in ROS and may result in apoptosis or sudden death of endothelial cells (20). Guo et al. (21) showed that the increase in superoxide radicals and decreased endothelial nitric oxide synthetase activity caused hair cell loss, thickening of the vascular intima and luminal stenosis in the spiral modiolus. Haubner et al. (22) also showed increased adhesion molecules in the vascular circulation of patients with ISSNHL. These studies found that endothelial dysfunction leads to impaired labyrinth perfusion and hearing loss in patients with ISSNHL, indicating the presence of vascular pathology in the etiopathogenesis of the disease.

Melatonin, a pineal secretory product of vertebrates, can be produce in many tissues and cells such as the cochlea (23,24). Melatonin has a neuroendocrinoimmunological role at the tissue level. It has both indirect antioxidant and direct free radical scavenger activity (24). Melatonin ensures these effects by transforming its metabolites, such as cyclic N-1-acetyl-5-methoxy kynuramine, 3-hydroxymelatonin and N-1-acetyl-N2-formyl-5-methoxykynuramine (25-27). All these metabolites neutralise free radicals. Moreover, studies demonstrated that melatonin induced several antioxidative enzymes, such as glutathione peroxidase, glutathione transferase and superoxide dismutase (28-32).

Melatonin has also been deliberated as a potent antihypertensive treatment. It may also enhance endothelial function by increasing the presence of nitric oxide, thereby exerting vasodilatory and hypotensive effects. Furthermore, it appears to be effective in disorders of the peripheral and central autonomic system by causing a decrease in the function of the adrenergic system and an increase in the cholinergic system (33). Melatonin application reduces the mean pulsatility sign of the internal carotid artery, systolic and diastolic blood pressure and norepinephrine levels (34). It also reduces blood pressure and decreases the catecholamine level in human subjects (35).

A study observed that aminoglycoside ototoxicity improved within 2 weeks, but when melatonin was added, it decreased to 5 days in rats (36). Melatonin as an antioxidant and immune modulator can be also used to treat cisplatin ototoxicity by trans-tympanic local administration in lower doses (37). Another study showed that free oxygen radicals are effective in the treatment of cochlear damage caused by noise, and melatonin plays a strong role in the protection of cochlear damage (38).

In this study, we investigated the relationship between serum melatonin levels and ISSNHL by taking into account the presence of antioxidant property, direct free radical scavenging activity and antihypertensive property of melatonin. In this study, we found that melatonin levels were significantly lower in patients with ISSNHL than in the control group, and a statistically significant result was obtained. Moreover, a statistically significant strong negative correlation was found between serum melatonin level and the severity of hearing loss.

The results of this study were limited by the small sample size. Nevertheless, we think that the study findings will help in the development of future treatment methods for ISSNHL.

Conclusion

This study indicates that low serum melatonin levels may be associated with ISSNHL. Serum melatonin levels of patients with ISSNHL were lower than controls. A larger series of studies are required to elaborate on this relationship.

Ethics

Ethics Committee Approval: The study was approved by the ethics committee of Zeynep Kamil Women’s and Children’s Diseases Training and Research Hospital (Protocol number: 109, date: 27.06.2018).

Informed Consent: Written informed consent was obtained from the patients.

Peer-review: Internally and externally peer reviewed.

Authorship Contributions

Conflict of Interest: No conflict of interest was declared by the authors.

Financial Disclosure: The authors declared that this study received no financial support.
