Introduction

Acute appendicitis (AA) is the most common cause of acute abdomen requiring surgical treatment (1). Appendectomy is one of the most common surgeries performed in general surgery practice, and the indication is often AA (2). While the lifetime probability of getting the diagnosis of AA is 8.6% in men and 6.7% in women, this probability is 12% in men and 25% in women for undergoing appendectomy (3). AA often occurs as a result of obstruction of the lumen of the appendix due to fecalith or lymphoid tissue hypertrophy; however, parasitic infestations such as Enterobius vermicularis may rarely cause AA (4). Enterobius vermicularis is known as the most common helminthic infestation among gastrointestinal infections worldwide (5). The relationship between Enterobius vermicularis infestation and appendicitis was first described in 1899 (6). In our patient, we aimed to present the Enterobius vermicularis infestation in a 36-year-old female patient who was operated with a pre-diagnosis of AA.

Case Report

A 36-year-old female patient presented to the emergency department with complaints of abdominal pain, nausea and loss of appetite for the last two days. On physical examination, there was defense, rebound and tenderness in the right lower quadrant of her abdomen. In laboratory tests; white blood cell count was 11,800 10³/mL, hemoglobin level was 14.5 g/dL, hematocrit was 41.9%, and other biochemical parameters were evaluated in the normal range. Appendix could not be visualized in ultrasonography. In abdominal computed tomography, it was detected that Enterobius vermicularis was located in the appendix. Histopathological examination of the appendix specimen showed signs of acute appendicitis and Enterobius vermicularis infestation.
evaluated that there was a blunt-ending tubular structure with an increased wall thickness and an inflamed appearance in the right paraceal region, which was separating from the cecum and extending to the subhepatic area (findings compatible with AA) (Figure 1).

A laparoscopic appendectomy decision was made for the patient. Consent was obtained from the patient for the operation. In the intraoperative exploration, it was observed that the wall thickness increased at the level of the cecum. The appendix with extensive mesenteric inflammation and serous free fluid around it and with increased wall thickness, extending retroceally to the subhepatic area, was detected. Laparoscopic appendectomy was performed. There were no intraoperative complications. On the first postoperative day, oral regimen was started after the passing of gas and stool, and the patient could tolerate the oral regimen. The patient was discharged on the third postoperative day. Postoperative pathology specimen was found to have Enterobius vermicularis in the lumen of the appendix, and findings compatible with AA were found (Figure 2). The patient and her family relatives were referred to the clinic of infectious diseases for anthelmintic treatment.

Discussion

AA is one of the most common causes of emergency surgery today (7). The gold standard method in its treatment is appendectomy. Although Enterobius vermicularis infestation is seen in all age groups, its prevalence is higher in childhood (8). Its spread in humans is most common through the fecal-oral route (9). The most common locations of the infestation are appendix and cecum lumen (10). It is more common in women than in men (11). The overall incidence of Enterobius vermicularis in patients with AA is between 0.2% and 4% (12). It is generally thought to cause mechanical obstruction in the lumen or cause a colic condition secondary to hypersensitivity (13).

It should be kept in mind that Enterobius vermicularis infestation may be present in the patient’s history in the preoperative period. A careful pathological examination to be made in the post-operative period will have important contributions to the treatment process of the patient and his/her relatives.

Anthelmintic treatment and laboratory examinations should be performed in all family members in a patient with Enterobius vermicularis infestation, because there is a risk of transmission among the family members of the patient.

Enterobius vermicularis is a rare cause in the etiopathogenesis of AA, and antiparasitic treatment should be planned for the patients and their relatives living in the same house, who have positive parasitic examinations in the postoperative period.
