Secondary Involvement of the Penis by Non-Hodgkin Lymphoma

Non-Hodgkin Lenfomanın İnfiltrasyonuna Sekonder Penis Tutulumu

Case Report

A 58-year-old male presented with penis pain and erectile dysfunction; he had a history of NHL for 4 years, and he was getting chemotherapy. His physical examination indicated a dysmorphic penile shaft, and the prostate was hard. The clinician suspected Peyronie’s disease. Routine blood, liver and renal function tests were normal. His urine leukocyte level was high [12 high pass filter (HPF); normal 0-5 HPF]. Multiple enlarged inguinal lymph nodes and minimal abdominal tenderness were noted. Abdominal ultrasound showed hepatomegaly, hepatosteatosis and normal configuration of both kidneys. MRI of the pelvis and penis showed isointense on T1 weighted imaging and hypointense on T2 weighted imaging signal changes and homogenous contrast enhancement on post-contrast T1 images.
in the corpus spongiosum of the penis (Figure 1, 5). Diffusion-weighted imaging shows restricted diffusion (Figure 2). Also, the central and peripheral zone of the prostate and left seminal vesicle were involved (Figure 3, 4). Bilateral obturator, external and inguinal lymph nodes were enlarged. With these findings, the diagnosis of penile lymphoma due to the involvement of the penis by NHL was established. And his treatment (systemic chemotherapy), which he had already taken, was continued. After chemotherapy, clinical response was observed. The symptoms of the patients were all reduced.

Figure 1. (A) Axial T1 weighted image showed homogeneous isointensity in the corpus spongiosum penis and (B) axial T2 weighted image showed hypointensity of the corpus spongiosum. (C) axial fat sat T1 weighted image and (D) axial fat sat T1 postcontrast image showed homogenous contrast enhancement in the corpus spongiosum of penis

Figure 2. (A) Axial T1 weighted image and (B) axial T2 weighted image showed enlarged bilateral obturator and inguinal lymph nodes. (C) Axial fat sat T1 weighted image and (D) axial fat sat T1 postcontrast image showed homogenous contrast enhancement on this lymph nodes

Figure 3. Axial Diffusion weighted images (A-B) in the corpus spongiosum and (C-D) prostate and left seminal vesicle shows diffusion restriction

Figure 4. (A) Axial T1 weighted image showed enlarged inguinal lymph nodes and (B) axial fat sat T1 postcontrast image showed homogenous contrast enhancement in this lymph nodes. Axial Diffusion weighted images (C-D) left inguinal lymph nodes, prostate and left seminal vesicle shows diffusion restriction

Figure 5. (A) Sagittal T1 weighted image showed homogeneous isointensity in the corpus spongiosum of penis and (B) Sagittal fat sat T1 postcontrast image showed homogenous contrast enhancement in the corpus spongiosum of penis
Discussion

NHL is generally observed in large, conglomerated lymph nodes. However, it can also occur outside the lymph nodes, called extra-nodal lymphoma. Extra-nodal lymphoma can also be seen in the gastrointestinal tract, liver, spleen, Waldeyer’s lymphatic ring, skin, central nervous system, bone, thyroid gland and the urogenital system, although with low probability (7). Primary penile lymphoma is extremely rare, with less than 30 cases reported in the literature. Secondary involvement of the penis can occur due to retrograde spread or to direct extension from the neighbouring organ (5). The affected locations are the penile shaft (most common) and glans penis (4,6). Lymphoma of the penis can present as a nodule, painless mass, plaques or ulcers and results in a dysmorphic appearance of the penile shaft. Painless mass is the most common symptom, followed by the ulcer (1). When the corpus cavernosum of the penis is involved, erectile dysfunction and penile swelling can be seen. Radiological modalities such as CT, MRI and PET CT should be undertaken for treatment and prognosis. MRI of most penile cancers shows superficial, hypointense infiltrative soft-tissue masses on T1- and T2-weighted imaging (2). After intravenous contrast injection, lesions enhance homogeneously. In the present case, after an early consideration of the diagnosis of Peyronie’s disease, the final diagnosis of NHL of the penis was confirmed by MRI images (6).

Systemic chemotherapy is the treatment of choice for the second presentation of lymphoma in the penis. Chemotherapy has the clear advantage of obtaining good cosmetic and functional results (1). Radical surgery can also be used, but only after the failure of other modalities like local radiotherapy, immunotherapy and combined modalities (3).

In conclusion, the penile malignant tumour and penile lymphoma are very rare and can be mistaken for other soft-tissue tumours, and hence it poses a significant differential diagnostic challenge (2). If the patient diagnosed with squamous cell carcinoma of the penis, treatment typically consists of radical penectomy (3,8). Excision biopsy is essential to reach the final diagnosis (7). Other differential diagnosis includes vasculitis, trauma nad sexually transmitted disease (1).

MRI plays a vital role in diagnosing penile lymphoma and assessing the local extent of the disease.
